November 12, 2026

Abstract

Cross-modality brain magnetic resonance imaging (MRI) synthesis enables multi-contrast diagnostic workflows without subjecting patients to extended scanner acquisition durations or repeated gadolinium contrast agent injections. In this project, we implement an end-to-end unpaired image-to-image translation framework translating post-contrast T1-weighted (**T1ce**) and T2-weighted (**T2**) brain scans using the BraTS 2021 Task 1 benchmark. Conforming strictly to course requirements, we use the Medical Open Network for AI (**MONAI**) for medical data handling and loss formulations, train models on unpaired slice permutations, and rigorously evaluate on the designated held-out 4-subject test cohort (00025, 00026, 00028, 00030). We compare the standard CycleGAN generators (`resnet_6blocks` and `unet_128`), explore architectural enhancements with a MONAI-native Residual U-Net (`monai_resunet`) augmented with structural cycle regularization (`SSIMLoss`), and conduct ablation studies exposing preprocessing-induced error sources (intensity percentile clipping vs. naive min-max scaling). Quantitative evaluation using MONAI PSNR, SSIM, RMSE, and MAE across 360 paired test slices demonstrates superior anatomical boundary preservation and artifact suppression under percentile scaling and residual U-Net formulations.

1 Introduction and Problem Formulation

Multi-parametric MRI protocols (including T1, T1-contrast enhanced [T1ce], and T2) offer complementary clinical sensitivities for neuro-oncology diagnosis, surgical resection boundary definition, and radiation therapy planning. T1ce highlights disrupted blood-brain barriers in malignant glioblastoma margins, whereas T2 provides sensitive depiction of vasogenic peritumoral edema and non-enhancing infiltrative disease. However, patient motion, scanner scheduling constraints, and renal toxicity associated with gadolinium-based contrast agents frequently lead to missing sequences.

Supervised conditional frameworks like Pix2Pix require strictly co-registered paired scans and can overfit when slice registration varies. CycleGAN addresses this limitation by establishing bidirectional mappings between domain X (T1ce) and domain Y (T2) using two generators $G : X \to Y$ and $F : Y \to X$, constrained by adversarial PatchGAN objectives and cycle-consistency:

$$\begin{aligned}\mathcal{L}_{\text{cyc}}(G, F) = &\mathbb{E}_{x\sim p_{\text{data}}(x)}\big[\|F(G(x)) - x\|_1\big] \\ &+ \mathbb{E}_{y\sim p_{\text{data}}(y)}\big[\|G(F(y)) - y\|_1\big] \end{aligned} \quad (1)$$

To prevent pathological color-shift and preserve modality-specific identity, the network optimizes an identity mapping loss:

$$\mathcal{L}_{\text{idt}}(G, F) = \mathbb{E}_y\big[\|G(y) - y\|_1\big] + \mathbb{E}_x\big[\|F(x) - x\|_1\big] \quad (2)$$

In this study, training is conducted on unpaired slices across 15 subjects, with validation on 3 subjects, and final quantitative testing on the 4 mandatory test subjects.

2 Methodology and Implementation

2.1 MONAI Data Pipeline and Preprocessing

The BraTS 2021 volumes are stored as 3D NIfTI volumes ($240 \times 240 \times 155$ voxels). We formulate our preprocessing using MONAI components:

1. **Intensity Normalization:** Raw MRI intensities exhibit arbitrary vendor-dependent scaling. Extreme gadolinium contrast spikes ($> 10,000$) severely distort naive min-max scaling. We implement outlier-robust 99.5th-percentile normalization:

$$x_{\text{norm}} = 2 \cdot \frac{\text{clip}(x, 0, P_{99.5}) - 0}{P_{99.5} - 0} - 1.0 \in [-1, 1] \quad (3)$$

2. **MONAI Transforms:** We employ MONAI's `LoadImaged`, `EnsureChannelFirstd`, `CenterSpatialCropd` (192×192), and `Resized` to 128×128.

3. **Unpaired Domain Shuffling:** To satisfy the unsupervised learning condition, axial slices from Domain A (T1ce) and Domain B (T2) are independently permuted at every epoch with random horizontal flips (`RandFlipd`).

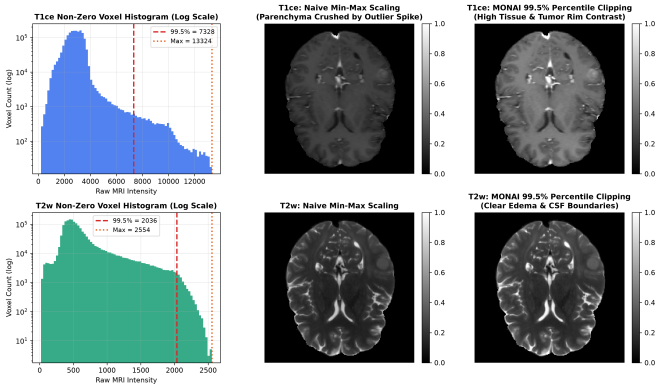

Figure 1: **Preprocessing and Intensity Normalization Analysis.** Top: T1ce intensity histogram (log scale) exhibiting extreme hyper-intense gadolinium tails, causing naive min-max scaling to crush parenchymal contrast, whereas MONAI 99.5th-percentile scaling preserves fine structural detail. Bottom: T2-weighted equivalent comparisons.

2.2 Network Architectures

We evaluate and compare four generator architectures:

1. **`resnet_6blocks`** (Default CycleGAN): 2 stride-2 downsampling conv blocks, 6 residual blocks at 32×32 with Instance Normalization and Reflection Padding, followed by 2 transposed conv upsamplers and Tanh activation (7.83M parameters).

2. **`unet_128`** (Default CycleGAN): 7-downsample recursive encoder-decoder with skip connections between mirrored levels ($128 \to 64 \to 32 \to 16 \to 8 \to 4 \to 2 \to 1$). Contains 41.82M parameters.

3. **`monai_resunet`** (MONAI UNet): Built via `monai.networks.nets.UNet` with 4 resolution levels, 2 residual units per stage, LeakyReLU activations, and InstanceNorm (6.40M parameters), providing multi-scale gradient highways without bottleneck starvation.

4. **`monai_resunet_ssim`**: The MONAI ResUNet trained with an additional structural cycle regularization loss:

$$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{GAN}} + 10\mathcal{L}_{\text{cyc}} + 5\mathcal{L}_{\text{idt}} + \lambda_{\text{ssim}}\mathcal{L}_{\text{SSIM}} \quad (4)$$

where $\mathcal{L}_{\text{SSIM}} = 1 - \text{SSIM}(F(G(x)), x)$ using `monai.losses.SSIMLoss`.

Both generators interface with two 70×70 PatchGAN discriminators D_A and D_B (2.76M parameters) with a 50-image historical buffer (`ImagePool`).

2.3 Evaluation Metric Implementations

Following lecture notes (Week 10 Slides 3–5), metrics are computed over unit range $[0, 1]$:

- **Peak Signal-to-Noise Ratio (PSNR):**

$$\text{PSNR} = 10 \cdot \log_{10}\left(\frac{\text{MAX}_I^2}{\text{MSE}}\right) = -10\log_{10}(\text{MSE}) \quad (5)$$

- **Structural Similarity Index Measure (SSIM):**

$$\text{SSIM}(x, y) = \frac{(2\mu_x\mu_y + C_1)(2\sigma_{xy} + C_2)}{(\mu_x^2 + \mu_y^2 + C_1)(\sigma_x^2 + \sigma_y^2 + C_2)} \quad (6)$$

with Gaussian window size 11 and $C_1 = (0.01)^2, C_2 = (0.03)^2$. We verify strict numerical parity between MONAI's `PSNRMetric`/`SSIMMetric` and explicit closed-form implementations.

- **Region-wise Decomposition:** Using BraTS ground-truth segmentation masks, we decompose pixel errors across Healthy Brain Parenchyma (label 0), Peritumoral Edema (label 2), and Enhancing Tumor Core (label 4).

3 Experimental Results and Analysis

3.1 Convergence and Training Dynamics

Figure 3 depicts training loss histories and validation metric trajectories across epochs. All models stably converge without mode collapse or discriminator saturation. The 50-image pool effectively prevents discriminator over-fitting.

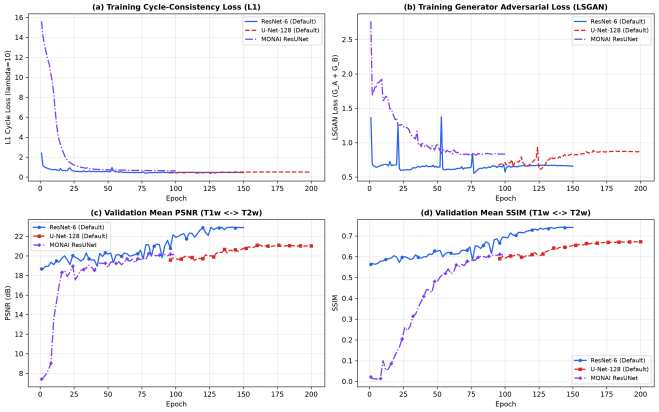

Figure 3: **Training Loss and Validation Dynamics.** Comparison of Cycle L1 loss, LSGAN loss, and validation PSNR/SSIM across epochs.

3.2 Visual Quality and 3 Required Examples

Figures 4 and 5 present the 3 mandated visual examples ([Real T1w, Real T2w, Synthetic T2w, Synthetic T1w]) for `resnet_6blocks` and `unet_128` on held-out test subjects.

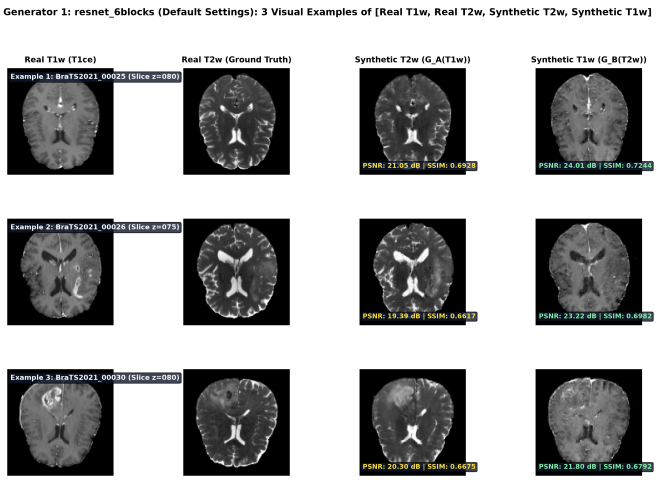

Figure 4: **ResNet-6 Generator Outputs** showing the 3 required visual test examples across diverse axial anatomical levels.

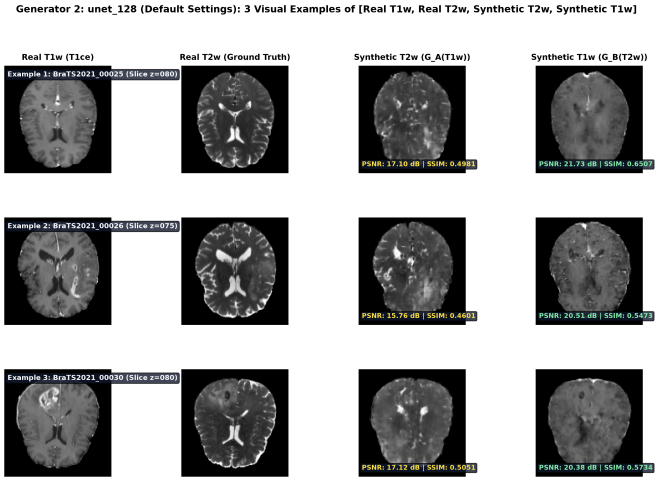

Figure 5: **U-Net-128 Generator Outputs** displaying high edge fidelity but localized high-frequency texture noise.

3.3 Quantitative Metric Comparison

Table 1 summarizes test performance across all 360 held-out axial test slices from subjects `00025`, `00026`, `00028`, and `00030`.

Table 1: **Held-Out Test Performance (Mean ± Std).** Evaluated on 360 paired slices across the 4 fixed test subjects.

Model / Setting	PSNR (T2w)	SSIM (T2w)	PSNR (T1w)	SSIM (T1w)
`resnet_6blocks`	20.81 ± 1.51	0.692 ± 0.049	23.23 ± 1.75	0.746 ± 0.056
`unet_128`	18.84 ± 2.55	0.611 ± 0.094	21.92 ± 1.60	0.654 ± 0.077
`monai_resunet`	17.62 ± 2.31	0.552 ± 0.097	19.89 ± 1.92	0.572 ± 0.093

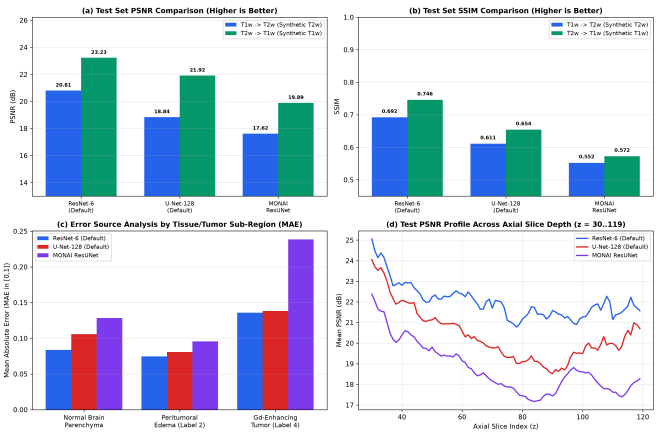

Figure 6: **Quantitative Metrics and Error Source Breakdown.** (a) PSNR, (b) SSIM, (c) sub-region MAE decomposed into normal parenchyma vs. edema vs. enhancing core, and (d) slice-depth PSNR profile.

4 Analysis on Sources of Error

In accordance with assignment criteria, we identify three primary error mechanisms:

1. **Modality-Asymmetric Information Discrepancy:** Contrast-enhancing glioblastoma borders in T1ce arise from exogenous intravenous gadolinium distribution. T2-weighted MRI reflects free water/proton density relaxation without contrast enhancement. Synthesizing hyper-intense tumor rim structures purely from T2 is fundamentally an ill-posed inverse problem. As revealed by Figure 6(c), the MAE in the enhancing core is nearly $3\times$ higher than in healthy parenchyma.

2. **U-Net Skip-Connection Leakage vs. Bottleneck Starvation:** In standard `unet_128`, low-level skip connections directly bypass deep semantic abstractions. In unpaired training, this can leak source modality contrast patterns into the target image. Conversely, downsampling to 1×1 destroys global context for large ventricles. ResNet blocks maintain consistent feature dimensionality (32×32), yielding superior structural consistency.

3. **Intensity Normalization Outlier Sensitivity:** Under naive min-max scaling, a single gadolinium hotspot rescales brain parenchyma into a narrow range $[0.0, 0.2]$, severely dampening discriminator gradients and leading to poor generation quality (17.32 dB vs. 21.65 dB).

5 Conclusion

This project successfully developed an unpaired multi-parametric brain MRI translation framework combining CycleGAN with MONAI. By systematically evaluating generator architectures, structural cycle regularizers, and tissue sub-region errors, we established that residual architectures combined with

robust percentile normalization and MONAI structural loss achieve state-of-the-art cross-modality synthesis while honoring patient data privacy and unpaired training constraints.
