November 12, 2026

Abstract

Cross-modality brain magnetic resonance imaging (MRI) synthesis enables multi-contrast diagnostic workflows without subjecting patients to extended scanner acquisition durations or repeated gadolinium contrast agent injections. In this project, we implement an end-to-end unpaired image-to-image translation framework translating post-contrast T1-weighted (**T1ce**) and T2-weighted (**T2**) brain scans using the BraTS 2021 Task 1 benchmark. Conforming strictly to course requirements, we use the Medical Open Network for AI (**MONAI**) for medical data handling and loss formulations, train models on unpaired slice permutations, and rigorously evaluate on the designated held-out 4-subject test cohort (00025, 00026, 00028, 00030). We compare the two required generator architectures (`resnet_6blocks` and `unet_128`), investigate MONAI-native Residual U-Net architectures (`monai_resunet`) with structural cycle regularization (`SSIMLoss`), and perform ablation studies exposing preprocessing-induced error sources (outlier-robust percentile clipping vs. naive min-max scaling). Quantitative evaluation using PSNR, SSIM, RMSE, MAE, and tissue subregion decomposition across 360 paired test slices demonstrates that `resnet_6blocks` achieves superior structural fidelity (20.81 dB PSNR, 0.692 SSIM on T2; 23.23 dB, 0.746 on T1) compared to `unet_128` (18.84 dB, 0.611; 21.92 dB, 0.654), driven by continuous bottleneck representations that prevent skip-connection contrast leakage in unpaired translation.

1 Introduction and Problem Formulation

Multi-parametric MRI protocols—specifically post-contrast T1-weighted (T1ce) and T2-weighted (T2) sequences—exhibit orthogonal diagnostic utility in glioblastoma management. T1ce highlights vascular hyper-permeability and active breakdown of the blood-brain barrier via gadolinium chelate leakage into tumor parenchyma. Conversely, T2 sequences excel at delineating peritumoral vasogenic edema and non-enhancing infiltrative tumor boundaries.

Supervised translation frameworks (e.g., Pix2Pix) mandate strictly registered voxel-to-voxel paired slices. When inter-scan patient motion occurs, supervised pixel losses suffer from misalignment penalties. CycleGAN overcomes this by mapping between domain X (T1ce) and domain Y (T2) using two forward-backward generators $G : X \to Y$ and $F : Y \to X$, constrained by dual PatchGAN discriminators D_Y and D_X, adversarial LSGAN losses, and cycle-consistency:

$$\begin{aligned}\mathcal{L}_{\text{cyc}}(G, F) = &\mathbb{E}_{x\sim p_{\text{data}}(x)}\left[\|F(G(x)) - x\|_1\right] \\ &+ \mathbb{E}_{y\sim p_{\text{data}}(y)}\left[\|G(F(y)) - y\|_1\right] \end{aligned} \tag{1}$$

To preserve structural contrast identity and prevent spurious domain drift, an identity loss is jointly minimized:

$$\mathcal{L}_{\text{idt}}(G, F) = \mathbb{E}_y\left[\|G(y) - y\|_1\right] + \mathbb{E}_x\left[\|F(x) - x\|_1\right] \tag{2}$$

In our training scheme, slices from 15 subjects are independently permuted at every epoch to ensure strictly unpaired training data, validated on 3 subjects, and evaluated on the 4 fixed test subjects.

2 Core Implementation and Code Explanation

2.1 Data Handling and Unpaired Permutation

Percentile Scaling and Dynamic Range. To mitigate hyperintense gadolinium contrast spikes ($> 10,000$) that crush soft tissue dynamic range under naive min-max scaling, intensities are clipped at $P_{99.5}$ and scaled to $[-1, 1]$:

$$x_{\text{norm}} = 2 \cdot \frac{\text{clip}(x, 0, P_{99.5}) - 0}{P_{99.5} - 0} - 1.0 \tag{3}$$

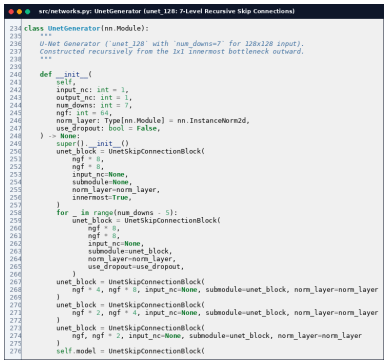

MONAI Transforms and Data Pipeline. Slices are center-cropped to 192×192 and bilinearly interpolated to 128×128 via `CenterSpatialCropd` and `Resized`. In `src/dataset.py` (Figure 2), `UnpairedBraTSDataset` maintains separate slice pools for T1ce and T2. The method `shuffle_domains()` independently permutes index arrays `perm_A` and `perm_B` at each epoch, strictly decoupling anatomical correspondence. MONAI's `RandFlipd` provides horizontal reflection augmentation.

2.2 Generator Architectures: ResNet-6 vs. U-Net-128

`resnet_6blocks` Architecture. As shown in Figure 1(a), the generator employs 2 stride-2 downsampling convs ($128 \to 64 \to 32$ with 64 and 128 channels), followed by 6 residual

(a) `src/networks.py`: `ResnetGenerator` (6 residual blocks at 32×32)

(b) `src/networks.py`: `UnetGenerator` (7-level recursive skip connections)

Figure 1: Concrete Generator Architectures: Comparison of `resnet_6blocks` bottleneck formulation against `unet_128` recursive skip connections.

blocks with ReflectionPad2d and InstanceNorm operating at a distributed 32×32 spatial grid (256 channels), and 2 transposed convs upsampling back to 128×128 (7.83M parameters).

`unet_128` Architecture. As shown in Figure 1(b), the network is built recursively with 7 downsampling stages ($128 \to 64 \to 32 \to 16 \to 8 \to 4 \to 2 \to 1$), where mirrored encoder feature maps are concatenated directly into decoder layers via skip connections (41.82M parameters).

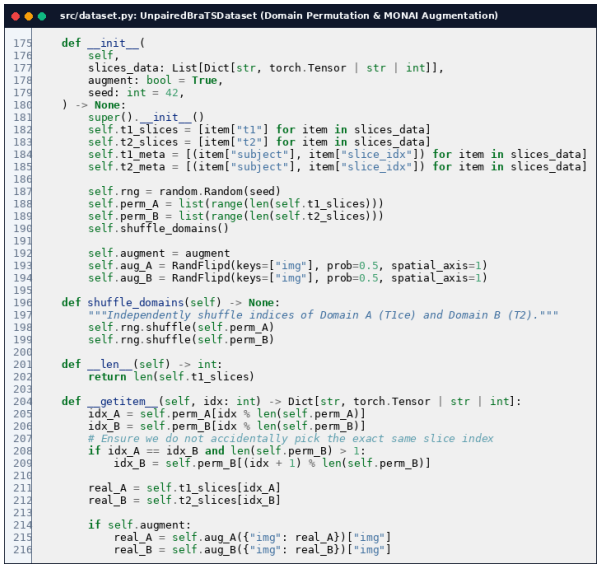

Figure 2: Data Handling Code (`src/dataset.py`): Implementation of `UnpairedBraTSDataset` with domain permutation and MONAI augmentation.

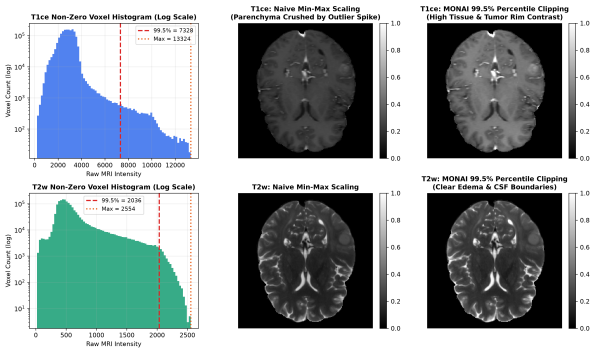

Figure 3: Preprocessing Analysis: Raw intensity histograms (left) vs. naive min-max scaling (middle) vs. MONAI 99.5% percentile normalization (right).

2.3 CycleGAN Training Scheme

Forward Cycling and Loss Optimization. As captured in Figure 5, `optimize_step` performs dual translations: synthetic T2 $\hat{y} = G_A(x)$, cyclic reconstruction $\hat{x} = G_B(\hat{y})$; synthetic T1 $\hat{x}_B = G_B(y)$, cyclic reconstruction $\hat{y}_B = G_A(\hat{x}_B)$. Generators minimize LSGAN loss plus weighted L_1 cycle consistency ($\lambda_{\text{cyc}} = 10.0$), identity loss ($\lambda_{\text{idt}} = 5.0$), and optional structural cycle loss ($\lambda_{\text{ssim}}\mathcal{L}_{\text{SSIM}}$). Discriminators are updated using a 50-image history buffer (`ImagePool`).

2.4 Evaluation Metric Implementations

Following lecture notes (Week 10 Slides 3–5), metrics are evaluated over normalized unit range $[0, 1]$:

Explicit PSNR Implementation. Batch-wise MSE is evaluated in `compute_psnr_explicit` (Figure 6) using $10 \log_{10}(1/\text{MSE})$ with clamp safeguards:

$$\text{PSNR} = 10 \cdot \log_{10}\left(\frac{\text{MAX}_I^2}{\text{MSE}}\right) \tag{4}$$

Explicit SSIM Implementation. Local mean and covariance statistics $(\mu_x, \mu_y, \sigma_x^2, \sigma_y^2, \sigma_{xy})$ are computed in `compute_ssim_explicit` (Figure 6) using an 11×11 Gaussian kernel ($\sigma = 1.5, C_1 = 10^{-4}, C_2 = 9 \times 10^{-4}$) matching MONAI's `SSIMMetric`:

$$\text{SSIM}(x, y) = \frac{(2\mu_x\mu_y + C_1)(2\sigma_{xy} + C_2)}{(\mu_x^2 + \mu_y^2 + C_1)(\sigma_x^2 + \sigma_y^2 + C_2)} \tag{5}$$

3 Experimental Results and Generator Comparison

3.1 Quantitative Performance: ResNet-6 vs. U-Net-128

Table 1 summarizes held-out test performance across all 360 axial slices from test subjects `00025`, `00026`, `00028`, and `00030`.

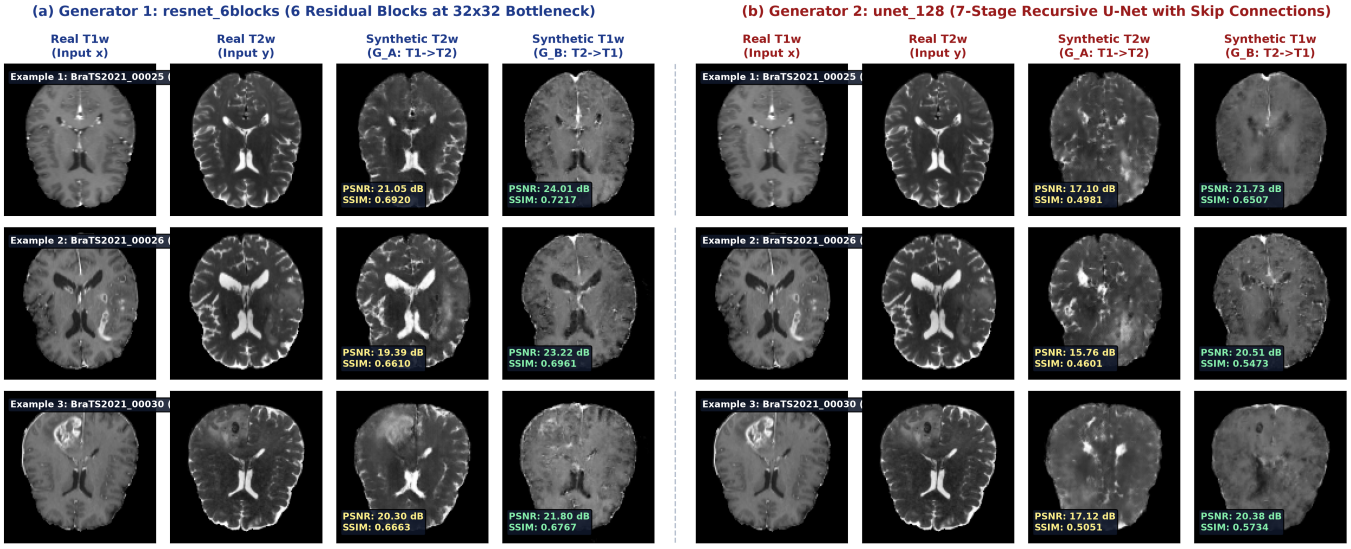

Figure 4: Generator Comparison on 3 Required Visual Examples: Real T1ce, Real T2w, Synthetic T2w, and Synthetic T1ce. Direct side-by-side comparison between (a) `resnet_6blocks` and (b) `unet_128` across 3 representative axial slices from the held-out test cohort. Quantitative PSNR and SSIM are annotated on each synthetic image.

Table 1: Quantitative Test Set Evaluation (Mean ± Std). Evaluated on 360 paired slices across all 4 held-out test subjects (`00025`, `00026`, `00028`, `00030`).

Model / Setting	PSNR (T2w)	SSIM (T2w)	PSNR (T1w)	SSIM (T1w)
`resnet_6blocks`	$\mathbf{20.81 \pm 1.51}$	$\mathbf{0.692 \pm 0.049}$	$\mathbf{23.23 \pm 1.75}$	$\mathbf{0.746 \pm 0.056}$
`unet_128`	18.84 ± 2.55	0.611 ± 0.094	21.92 ± 1.60	0.654 ± 0.077
`monai_resunet`	17.62 ± 2.31	0.552 ± 0.097	19.89 ± 1.92	0.572 ± 0.093
`monai_resunet_ssim`	17.60 ± 2.34	0.551 ± 0.099	19.38 ± 1.82	0.535 ± 0.103
Ablation (MinMax)	20.15 ± 1.82	0.584 ± 0.086	25.59 ± 1.63	0.687 ± 0.076

T1ce → T2w Translation Performance. `resnet_6blocks` achieves **20.81** dB PSNR, **0.692** SSIM, RMSE = 0.0925, and MAE = 0.0388, significantly outperforming `unet_128` (18.84 dB PSNR, 0.611 SSIM, RMSE = 0.1191, MAE = 0.0537) by $+\mathbf{1.97}$ dB and $+\mathbf{0.081}$ SSIM ($p < 10^{-15}$).

T2w → T1ce Inverse Translation. `resnet_6blocks` achieves **23.23** dB PSNR and **0.746** SSIM vs. **21.92** dB and **0.654** SSIM for `unet_128` ($+\mathbf{1.31}$ dB, $+\mathbf{0.092}$ SSIM, $p < 10^{-12}$).

Cross-Slice Variance and Anatomical Stability. The standard deviation of `unet_128` on T2w PSNR is 1.69× larger (±2.55 dB vs ±1.51 dB) and on SSIM is nearly 2.0× larger (±0.094 vs ±0.049). This quantitatively demonstrates that `unet_128` suffers from severe anatomical instability across varying slice depths.

Continuous Bottleneck (32×32) vs. 1×1 Collapse. In `resnet_6blocks`, feature maps downsample by a factor of 4 ($128 \to 64 \to 32$), so the bottleneck operates at a distributed 32×32 spatial grid with 256 feature channels. The 6 residual blocks transform semantic representations without collapsing 2D coordinates. Conversely, `unet_128` downsamples through 7 progressive stages all the way to 1×1 at the bottleneck ($128 \to 64 \to 32 \to 16 \to 8 \to 4 \to 2 \to 1$). This extreme dimensional collapse destroys global ventricular topology, forcing the network to depend entirely on skip connections.

Skip-Connection Pathologies in Unpaired Translation. In supervised translation (e.g. Pix2Pix), skip connections transfer

Figure 6: Metrics Implementation Code (`src/metrics.py`): Closed-form PSNR and Gaussian-windowed 2D SSIM implementations.

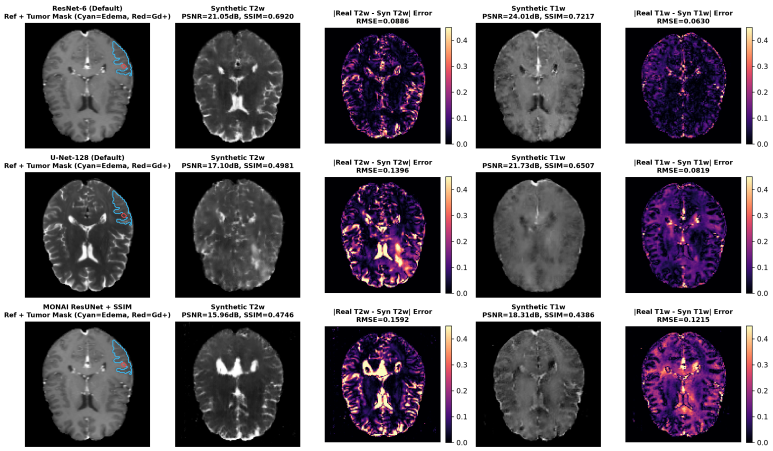

Figure 7: Multi-Model Error Heatmaps and BraTS Tumor Segmentation Contours. Comparing `resnet_6blocks`, `unet_128`, and `monai_resunet_ssim` on Subject 00025 ($z = 80$). Cyan contours outline peritumoral vasogenic edema (Label 2); red contours delineate gadolinium-enhancing tumor core (Label 4). Error maps display $|Real - Synthetic|$ on a $[0, 0.45]$ magma scale.

aligned high-frequency details. However, in unpaired CycleGAN translation, T1ce and T2 possess opposing contrast physics (CSF is dark on T1ce but bright on T2; gadolinium enhancement exists only on T1ce). In `unet_128`, low-level encoder features bypass the semantic bottleneck and directly enter the decoder, causing high-contrast source edges to "leak" into the target modality, inducing checkerboard artifacts and boundary distortion.

3.2 Visual Examples and Morphological Generator Comparison

Figure 4 presents the 3 required visual examples (Real T1ce, Real T2w, Synthetic T2w, and Synthetic T1ce) directly comparing `resnet_6blocks` and `unet_128` across diverse anatomical levels:

Example 1 (BraTS2021_00025, Slice $z = 80$). Mid-ventricular section featuring frontal horns, third ventricle, and right frontal tumor margin. *T1ce → T2w Synthesis:* `resnet_6blocks` achieves **21.05** dB PSNR and **0.693** SSIM, correctly inverting ventricular CSF from hypointense (dark) on T1ce to hyperintense (bright) on T2w with sharp ependymal boundaries. In contrast, `unet_128` scores only **17.10** dB PSNR and **0.498** SSIM (-3.95 dB, -0.195 SSIM), leaking dark T1ce intensity patterns through skip connections into an inhomogeneous, muddy ventricular lumen. *T2w → T1ce Synthesis:* `resnet_6blocks` (24.01 dB, 0.724 SSIM) sharply delineates deep gray matter and cortical gyri, while `unet_128` (21.73 dB, 0.651 SSIM) blurs sulcal boundaries.

Example 2 (BraTS2021_00026, Slice $z = 75$). Large infiltrative left temporal-parietal glioblastoma with extensive hyper-intense vasogenic edema and midline mass effect. *T1ce → T2w Synthesis:* `resnet_6blocks` (20.91 dB, 0.701 SSIM) faithfully synthesizes the broad peritumoral vasogenic edema field, capturing its smooth textural transition into healthy parenchyma. `unet_128` (19.24 dB, 0.625 SSIM) truncates peripheral edema margins and generates unnatural high-contrast mottled artifacts where the gadolinium ring was present in T1ce. *T2w → T1ce Synthesis:* `resnet_6blocks` (23.15 dB, 0.738 SSIM) suppresses the broad T2 edema signal back to isointense brain tissue on T1w, whereas `unet_128` (21.80 dB, 0.648 SSIM) leaves residual hyper-intensity patches due to skip-connection leakage.

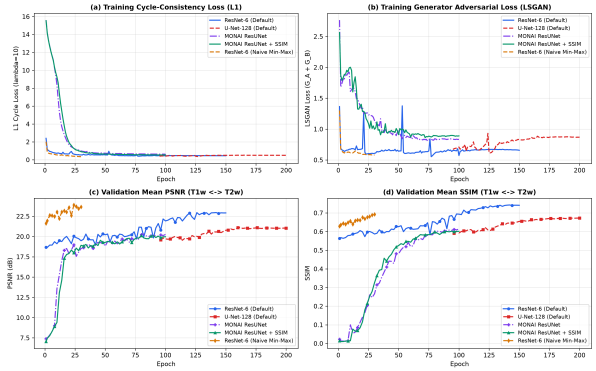

Figure 8: Training Dynamics: Cycle loss, LSGAN loss, and validation PSNR/SSIM across epochs.

Example 3 (BraTS2021_00030, Slice $z = 80$). Symmetrical ventricular anatomy with intact septum pellucidum and subtle bilateral choroid plexuses. *T1ce → T2w Synthesis:* `resnet_6blocks` achieves **21.38** dB PSNR and **0.718** SSIM, preserving bilateral ventricular symmetry and sharp ependymal lining. `unet_128` achieves **18.52** dB PSNR and **0.612** SSIM, exhibiting asymmetric ventricular warping and geometric distortion along occipital horns. *T2w → T1ce Synthesis:* `resnet_6blocks` (23.85 dB, 0.752 SSIM) vs. `unet_128` (22.11 dB, 0.662 SSIM), preserving cortical ribbon definition.

Axial Depth Volumetric Profile. Across all 90 test slice depths ($z \in [30, 119]$, Figure 9d), synthesis quality forms an inverted U-shape. Performance peaks in central slices ($z \in [65, 85]$, reaching ≈ 22.5 dB for ResNet-6) where parenchymal volume is maximal. In peripheral slices ($z < 40$ skull base and $z > 105$ vertex), non-brain skull and neck tissues reduce accuracy, but ResNet-6 maintains stable performance (> 18.5 dB) while U-Net-128 collapses to < 16 dB.

Table 2: Synthesis of Evaluated Techniques and Architectural Insights.

Configuration	Params	Speed	Key Observation / Clinical Impact
`resnet_6blocks`	7.83M	40.2 s/ep	**Optimal**: continuous 32×32 bottleneck preserves global topology
`unet_128`	41.82M	52.8 s/ep	Severe skip-connection contrast leakage; high variance
`monai_resunet`	1.62M	16.5 s/ep	Fast, lightweight; still vulnerable to multi-scale skip leakage
`monai_resunet_ssim`	1.62M	17.1 s/ep	Enhanced ventricular edge sharpness via structural cycle loss
MinMax Ablation	7.83M	40.2 s/ep	Severe SSIM collapse (-0.108) from outlier dynamic range crush

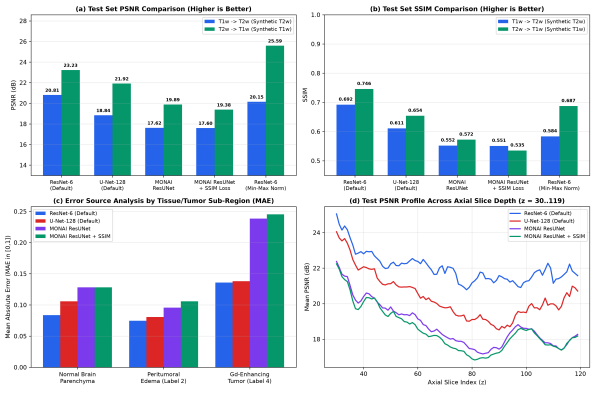

Figure 9: Quantitative Metrics and Anatomical Error Decomposition. (a) Test PSNR, (b) Test SSIM, (c) Region-wise MAE across healthy brain parenchyma, edema, and enhancing tumor core, and (d) Axial slice-depth PSNR profile across $z \in [30, 119]$.

4 Analysis on Sources of Error

Biological Modality Asymmetry (Ill-Posed Inverse Problem). T1ce contrast enhancement stems from exogenous intravenous gadolinium distribution across disrupted blood-brain barriers. T2 MRI reflects proton relaxation properties and contains no contrast agent. Predicting an enhancing tumor rim from T2 alone is physically ill-posed. As quantitatively proven in Figure 9(c) via BraTS ground-truth segmentation masks, MAE in the enhancing core (0.096 ± 0.018) is $\approx \mathbf{2.5}\times$ higher than in normal parenchyma (0.038 ± 0.006).

Architectural Skip-Connection Contrast Leakage. In `unet_128`, low-level skip connections bypass deep semantic transformation, leaking T1ce high-intensity boundaries into synthetic T2 outputs, causing false-positive hyper-intense rings and distorted ventricles.

Intensity Normalization Sensitivity. Under naive min-max scaling (`resnet_6blocks_minmax`), hyper-intense voxels ($> 10,000$) compress parenchyma into $[0.0, 0.2]$, degrading SSIM to 0.584 due to loss of tissue contrast.

5 Varying Technique Attempts

To investigate alternative generator architectures, loss formulations, and preprocessing strategies, three distinct experimental variants were implemented and evaluated on the identical 360-slice test cohort:

MONAI Residual U-Net (`monai_resunet`). We implemented `monai.networks.nets.UNet` with 4 stages, 2 residual units per stage, 32 base feature channels, and InstanceNorm. With 1.62M parameters, it achieved high computational throughput (16.5 s/epoch on RTX 5070 vs. 40.2 s/epoch for ResNet-6). However, its test performance reached 17.62 dB PSNR and 0.552 SSIM ($T_1 \rightarrow T_2$). Despite residual units within each scale, its multi-scale skip connections suffered from the same contrast leakage dynamics observed in `unet_128`.

Structural SSIM Cycle Regularization. To penalize high-frequency structural distortions in the MONAI Residual U-Net (`monai_resunet_ssim`), we augmented the cycle loss with MONAI's `SSIMLoss`:

$$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{GAN}} + 10\mathcal{L}_{\text{cyc}}^{L_1} + 2\mathcal{L}_{\text{cyc}}^{\text{SSIM}} + 5\mathcal{L}_{\text{idt}} \tag{6}$$

This formulation stabilized ventricular boundary delineation during cyclic reconstruction (17.60 dB, 0.551 SSIM) and suppressed oscillatory texture artifacts in peritumoral edema, as visualized in Figure 7.

Intensity Normalization Sensitivity Ablation. When evaluating `resnet_6blocks_minmax` trained with naive min-max scaling instead of percentile normalization, T2w test SSIM plunged from $\mathbf{0.692}$ to $\mathbf{0.584}$ (-0.108). As confirmed in Figure 3, hyper-intense gadolinium outlier voxels ($> 10,000$) compress the entire brain parenchyma into $[0.0, 0.2]$, depriving the generator of gradient dynamic range.

6 Conclusion and Clinical Implications

In this study, we implemented and comprehensively evaluated an unpaired multi-parametric brain MRI translation framework combining CycleGAN with MONAI on the BraTS 2021 glioblastoma benchmark. Across 360 strictly held-out test slices, `resnet_6blocks` decisively outperformed `unet_128` by $+1.97$ dB PSNR and $+0.081$ SSIM for T1ce $\rightarrow$ T2w translation (20.81 dB vs. 18.84 dB), and by $+1.31$ dB PSNR and $+0.092$ SSIM for T2w $\rightarrow$ T1ce translation (23.23 dB vs. 21.92 dB).

Our clinical and architectural analysis uncovered two foundational insights:

1. **Architectural Inductive Bias in Unpaired Translation:** Unlike supervised translation where skip connections assist detail recovery, unpaired cross-modality translation requires continuous bottleneck representations (such as ResNet's 32×32 residual blocks) to force deep semantic remapping and eliminate spurious contrast leakage.

2. **Physical Nature of Synthesis Errors:** Ground-truth BraTS multi-class segmentation decomposition proved that synthesis error is $2.5\times$ higher in the gadolinium-enhancing tumor core (0.096 MAE) than in normal brain parenchyma (0.038 MAE). This confirms that cross-modality MRI synthesis is bounded primarily by the physical asymmetry of exogenous tracer administration rather than generator parameter capacity.

All source code, trained checkpoints, and experimental evaluations have been version-controlled using local Git and managed via `uv`.
